Background

- The "right" amount and quality of openness may vary across networks (Grotevant, et al. 1994).
- Generally, greater openness has been associated with better psychological outcomes for network members (Ge, et al., 2008).
- Different aspects of openness have been shown to differentially affect members of the adoption kinship network (e.g. Cushman, et al., 1997; Dunbar et al., 2006).

Current Study

Aspects of Openness most related to Benefits?

Using multivariate techniques we examined multiple aspects of openness to estimate the relative influence they have on psychological outcomes.

Sample

- The Early Growth and Development Study (EGDS)
- A prospective longitudinal study in two cohorts (N=561 sets)
- Domestic, non-special needs, infant adoptions

Analyses

- Correlate and Regress different aspects of openness in adoption reported shortly after placement on psychological outcomes for network members 18 months post-placement.

Measures:

- Beck Depression Inventory
- Beck Anxiety Inventory
- Satisfaction with the Adoption Process
- Adjustment to the Adoption Process
- Contact frequency scales
- Knowledge amount scales

Results:

- For all respondents Contact and Knowledge were significantly correlated with Satisfaction. Regression analyses for each network role were run and are shown at the right in tables.
- Birth Mother & Father Depression was significantly and inversely correlated with report of Amount of Choice in Openness and amount of information about the adoptive mother’s mental health. Regression showed no significant associations.
- Birth Father Anxiety was significantly and negatively correlated with Choice in Openness.
- Adoptive Mother Depression was significantly correlated with knowledge of Birth Mother and Father but regressions were not significant.
- Adoptive Mother Anxiety was higher with more phone contact & lower with more face-to-face contact with Birth Mother. Anxiety was higher with receipt of more frequent Birth Father letters/emails. Regression results were significant.

Interpretation

1. Openness in Adoption is an important part of being satisfied with the adoption experience.
2. The relatively strong and significant negative association between satisfaction and knowing the reasons the Adoptive Mother is adopting may be indicative of a Birth Father’s sense of loss or shame and a sense of responsibility to care for his child. As Adoptive Mothers are moving forward accomplishing important developmental tasks for adults, this knowledge may stir basic emotions and challenge the Birth Father’s sense of self.
3. As she abdicates her role as “nurturer” a Birth Mother will want control to ensure her child is being raised by a healthy parent hence the significant associations between satisfaction and control and satisfaction and impressions of Adoptive Mother mental and physical health.
4. Adoptive Mothers and Fathers want to be prepared to help their child with any physical health issues by knowing about the birth parents’ health histories.
5. Adoptive Parents want to connect with the birth mother relinquishing her child to them to assure her of their intentions and be assured of her reasons for placing the child.
6. Adoptive mothers feel more secure in their role as mother when they know more about the cultural heritage and mental state of the birth father and have control over contact with him.

• These Interpretations need to be examined more closely through interviews with network members.

Acknowledgement

This project was supported by ROI HD042658. NICHD, NIDA, and the Office of the Director; NIH, U.S. PHS (PI Years 1–5: David Reiss; PI Years 6–10: Leslie D. Leve).

We would like to thank the birth and adoptive families who participated in this study and the adoption agencies who helped with the recruitment of study participants.
